Checking for existing GPG keys - GitHub Docs

2-3 minutes

Before you generate a GPG key, you can check to see if you have any existing GPG keys.

- Mac
- Windows
- Linux

Supported GPG key algorithms

Git Hub supports several GPG key algorithms. If you try to add a key generated with an unsupported algorithm, you may encounter an error.

- RSA
- ElGamal
- DSA
- ECDH
- ECDSA
- EdDSA

Note: GPG does not come installed by default on macOS or Windows. To install GPG command line tools, see GnuPG's Download page.

- 1. Open Terminal.
- 2. Use the gpg --list-secret-keys --keyid-format=long command to list the long form of the GPG keys for which you have both a public and private key. A private key is required for signing commits or tags.

Shell

```
gpg --list-secret-keys --keyid-format=long
```

Note: Some GPG installations on Linux may require you to use gpg2 --list-keys --keyid-format LONG to view a list of your existing keys instead. In this case you will also need to configure Git to use gpg2 by running git config --global gpg.program gpg2.

- 3. Check the command output to see if you have a GPG key pair.
 - If there are no GPG key pairs or you don't want to use any that are available for signing commits and tags, then generate a new GPG key.
 - If there's an existing GPG key pair and you want to use it to sign commits and tags, you can display the
 public key using the following command, substituting in the GPG key ID you'd like to use. In this
 example, the GPG key ID is 3AA5C34371567BD2:

```
$ gpg --armor --export 3AA5C34371567BD2
# Prints the GPG key ID, in ASCII armor format
```

You can then add your GPG key to your GitHub account.
